11	Historical information from 2019

### Introduction

Bean seed flies overwinter as pupae in the soil. In early spring (March-April), flies start to emerge and after feeding and mating, the female lays her eggs just below the soil surface, generally singly. Females may lay as many as 40 eggs in a day. There is generally a period of several days before a further batch of eggs is laid. In the absence of a suitable host plant, the larva is able to complete development by feeding on decomposing organic matter. The larvae pupate in the soil at varying depths. The rate of development, and therefore the number of generations, depends on the ambient temperature. Bean seed flies can complete between 3 and 6 generations during the year according to the climate. Females prefer to lay eggs in freshly disturbed soil, especially where there are residues of vegetable matter or where large amounts of farmyard manure have been applied. The presence of plants is not required for bean seed flies to lay eggs. Crops affected include: onion, bean, cucurbits, spinach, Brassica, radish, beet, asparagus and sweetcorn.

**A bean seed fly forecast has not been developed but the numbers captured in water traps at are recorded below.**

**We first set up the traps in some overwintered swedes at Wellesbourne but because of COVID-19 the traps are now in the village allotments and in a garden at Tysoe in south Warwickshire. They are now back at Wellesbourne.**
